

# Fiber optic networking does not require a splitter

## Overview

A passive optical network (PON) is a fiber-optic telecommunications network that uses only unpowered devices to carry signals, as opposed to electronic equipment. In practice, PONs are typically used for the last mile between Internet service providers (ISP) and their customers. A splitter is not a filter like a wavelength division multiplexer (WDM). Light power goes in and light power coming out of the various legs is reduced in. In a recent FBA 101 Series article, FBA defined several splitter architectures. Due to the wide range of deployment configurations, this document will provide qualitative differences, but no specific quantitative comparisons. Unlike active devices (which require power), splitters operate without electricity, relying solely on the physics of. Network designers and ISPs aiming for efficiency must focus on effective passive optical network design, with careful consideration of PON architecture planning and splitter placement. This “passive” nature makes it.
