

Optical Attenuator Accuracy

Overview

Optical attenuators are commonly used in fiber-optic communications, either to test power level margins by temporarily adding a calibrated amount of signal loss, or installed permanently to properly match transmitter and receiver levels. Sharp bends stress optic fibers and can cause losses. If a received signal is too strong a temporary fix is to wrap the cable around a pencil until the desired level is reached. Overview An optical attenuator, or fiber optic attenuator, is a device used to reduce the level of an optical signal, either in free space or in an optical fiber. The basic types of optical attenuators are fixed, step-wise variable, and continuously variable. The power reduction is done by such means as absorption, reflection, diffusion, scattering, deflection, diffraction, and dispersion, etc. Optical attenuators usually work by absorbing the light, like an optical absorber. Optical attenuators can take a number of different forms and are typically classified as fixed or variable attenuators. What's more, they can be classified as LC, SC, ST, FC, MU, E2000 etc. according to the different type.

What Is an Optical Attenuator and How Does It Work?

An optical attenuator is a passive device that reduces optical power in a controlled way without changing the signal format. In fiber systems, attenuation is specified in dB (a ratio), while ...
