

Optical splitter to IP

AI Overview

Optical splitters are passive devices in PON networks that divide a single optical signal from an OLT into multiple outputs, enabling IP-based connectivity to multiple end users without requiring dedicated fibers for each.

Role of Optical Splitters in PON

Optical splitters are passive devices that split a single input optical signal into multiple outputs, or combine multiple signals into one, without requiring power. In a Passive Optical Network (PON), splitters allow a single Optical Line Terminal (OLT) at the service provider's central office to serve multiple Optical Network Terminals (ONTs) at homes or businesses, efficiently distributing IP traffic over fiber. This enables point-to-multipoint connectivity, reducing the number of fibers and OLT ports needed while maintaining IP service delivery.

Split Ratios and Network Impact

Splitters are characterized by their split ratio, which defines how the input signal is divided among outputs. Common ratios include 1x2, 1x4, 1x8, 1x16, 1x32, and 1x64. Higher split ratios allow more users per OLT port but increase insertion loss, which can limit signal reach and require careful power budgeting. For example, a 1x32 splitter divides the signal among 32 outputs, reducing the optical power per output but still supporting IP traffic as long as the ONT receives sufficient power.
