

The optical splitter has a MAC code

AI Overview

Optical splitters themselves do not have a MAC address; MAC addresses are associated with the ONUs/ONTs connected downstream of the splitter.

Understanding Optical Splitters

Optical splitters are passive devices used in fiber networks to divide or combine light signals, enabling point-to-multipoint communication in FTTH networks such as GPON, XGS-PON, and GE-PON . They do not perform any network processing or communication functions, so they do not have a MAC address. Their role is purely optical, distributing signals from a single fiber to multiple fibers without adding network identifiers.

MAC Addresses in Fiber Networks

MAC addresses are unique identifiers assigned to Optical Network Units (ONUs) or Optical Network Terminals (ONTs), which are the active devices at the customer end of the network . These devices convert optical signals to electrical signals and handle network communication. In some advanced systems, technologies exist to capture the MAC addresses of ONUs even when they are connected below an optical splitter, by detecting upstream light that leaks from the fiber without affecting communication . This allows network operators to manage and identify individual ONUs efficiently.
